June 2019
Goals

• Describe measurements & instrumentation in cryogenic systems
• Give examples of typical temperature, pressure, flow and level sensors used in cryogenic systems
• Discuss the proper installation of sensors, wiring and feed throughs in cryogenic instrumentation
• Describe Thermal Acoustic Oscillations
The correct measurement of properties such as temperature, pressure, flow, level and vacuum in cryogenic systems is a key factor in the success of cryogenic systems.

Measurements will allow us to understand if our cryogenic components are working properly, enable us to control them and permit the collection of scientific data.

There are many subtleties in the selection and installation of cryogenic sensors.

- Poor sensor selection and installation can result in wildly inaccurate readings or sensor failure

Think about instrumentation as a complete system – sensor, wiring, feed through, DAQ rather than just the sensor itself.

- Total system cost per measuring point can be ~ $500 - $1000
Introduction

• Define system & sensor requirements:
  – Range
  – Accuracy
  – Time response
  – Sensor environment (e.g. presence of magnetic or radiation fields)
  – Precision – what is the smallest change detected by the sensor?
  – Reliability
  – Cost
Instrumentation Rules of Thumb

• Don’t use more accuracy & precision than required
• Use commercially produced sensors whenever possible – there is a lot available
• When possible, mount sensors outside cryostat at 300 K (e.g. pressure transducers, flow meters)
• For critical devices inside of cryostats, install redundant sensors whenever feasible
• Be sure to consider how to recalibrate sensors
• If at all possible avoid, cold instrumentation feed throughs
  – SNS experience
• Once R&D is done, minimize number of sensors in series production of cryostats
Temperature Measurement

• Measure some property – typically resistance or voltage drop that changes with temperature

• Commercial Temperature Sensing Options
  – Silicon Diodes (300 K - ~1 K)
  – Pt Resistors (300 K - ~ 30 K)
  – Ge Resistors (100 K < 1 K)
  – Carbon Glass resistors (300 K ~ 1 K) best below 100 K
  – Ruthenium Oxide (40 K - < 1 K )
  – Cernox (300 K < 1 K)
  – Thermocouples

• Take care not to put so much power in the sensor that it “self heats” and gives a false reading. Follow the vendor’s recomendations

*Note: DIY in the last column stands for Do It Yourself and can be quite expensive.*
Cernox Temperature Sensors
LakeShore Cryotronics

- Very responsive at LHe Temps
- Expensive
- Requires individual calibration for best results
- Very good in ionizing radiation environments
Can both be individually calibrated or used with typical curves
Relatively low cost, frequently used in cryogenic plants
Not suitable for radiation environments
Platinum Resistors

- Good down to ~ 30 K
- Works well in ionizing radiation fields
- Can be calibrated with good accuracy to common calibration curves
- Relatively low cost
- Excitation is generally 1 mA DC

From Lakeshore Cryotronics Catalog
Temperature Sensor Wiring

- Four wire measurements (V+, V-, I+, I-) should be used for temperature sensors to avoid impact of lead resistance on measurement.
- Wires should be in twisted pairs (V+, V-) and (I+, I-) to reduce noise pickup.
- Wires will connect from 300 K to cryogenic temperatures so must be have small cross sections, and low thermal conductivity.
  - 36 gage manganin wire is a frequent choice.
    - see thermal conductivity integrals
  - Avoid using wires that are too fine as this will result in breakage and poor reliability.
  - Heat sink wires at an intermediate temperature.
- Don’t over constrain the wires - allow room for movement and shrinkage during cool down to avoid breakage.
• Critical to the proper use of temperature sensors in vacuum spaces
  – You want to measure the temperature of the sensor not that due to heat leak down the wire
  – Small heat capacities at cryogenic temperatures means small heat leaks can easily impact sensor temperature
  – Heat sink wire at intermediate temperature and also at point where temperature is measured
Table 4-3 Wire heat-sinking lengths required to thermally anchor to a heat sink at temperature $T$ to bring the temperature of the wire to within 1 mK of $T$

Handbook of Cryogenic Engineering
Pressure Measurement

• Carry out at room temperature where possible (using a capillary tube)

• Problems with room temperature pressure measurement
  – Thermal Acoustic Oscillations (recall Lecture 13)
  – Time response will be too slow for high speed transients but for most operations this isn’t an issue
    • High speed pressure pulse due to magnet quenching is an exception

• Some cold pressure transducers exist that solve these problems

• There are a wide range of 300 K commercial pressure transducers that exist
  – Many are based on capacitive sensors or strain gage bridges mounted on diaphragms that change shape with pressure
300 K operation
Uses a capacitive sensor
Accurate up to 0.3 % of reading
Flow Measurements

- A variety of techniques are available mostly the same ones as used in standard fluid mechanics including:
  - Venturi Meters
  - Turbine Flowmeters
  - Coriolis Flowmeters
  - Orifice plate Flowmeters

- Comments
  - Insure that the devices are calibrated for operation at the temperatures and pressures that you are expecting (use appropriate fluid properties)
  - Beware of situations that can result in unplanned two-phase flow
  - Allow sufficient length for flow straightening if required (e.g. Venturi)
  - If possible install the flow meters in the 300 K portions of the flow
Note use of cold DP transducer
A more common approach is to use capillary tubes and a warm transducer

From The Handbook of Cryogenic Engineering
Tested down to 1.7 K at CERN LHC
Flow produces vibrations in the flow tubes that have a phase offset directly related to mass flow

From *Development of a mass flowmeter based on the Coriolis acceleration for liquid, supercritical and superfluid helium*

</table>

(1): Using a device with higher nominal flow rate, the pressure drop could be reduced in compensation the turn down is reduced too and the required installation space enlarged.

(2): There is no information in the literature about the long term experience at low temperature conditions.

(3): Pressure transducer, differential pressure transducer and temperature measurement necessary.

(4): Stationary flow conditions without any capillary effect.

(5): Upstream length enlarged factor 2 compared to Venturi tube.

(6): Upstream length reduced compare to Venturi tube.
Level Measurements

- Measuring the level of cryogenic baths is important to proper operations
- Options include:
  - Capacitance gauges (LN$_2$, LOX, LH$_2$)
  - Superconducting level probes (LHe)
    - Installing redundant or easily replaceable s/c level probes is highly recommended
  - Differential pressure techniques
  - Floats (LN$_2$)

S/C Liquid level probes
American Magnetics Inc
Feedthroughs

- Instrumentation feedthroughs are best done at 300 K
- Avoid cryogenic instrumentation feedthroughs if at all possible
  - If you can’t, significant testing and validation will be needed
- In test and prototype cryostats always put in more feedthroughs (or blank flanges) than you think you’ll need
- GHe at 300 K and 1 bar has poor dielectric strength
  - Use spacing of pins or potting of feedthrough if this will cause problems (e.g. in voltage taps of S/C magnets)
- Beware of possible thermal acoustic oscillations being set up in pressure taps and other sealed tubes
Thermal Acoustic Oscillations (TAOs)

- Occurs in a tube that connects room temperature and cryogenic temperatures and is sealed at the room temperature end.
- The thermal gradient establishes standing pressure oscillations in the fluid in the tube.
- These oscillations can cause very high pressure spikes as well significant heating at the low temperature end due to friction.
- This can cause significant problems in cryogenic systems.
- Such scenarios should be avoided but the enabling geometry is fairly common in cryogenic systems.
  - Valved off lines
  - Pressure taps
  - Instrumentation
- There have been studies to determine stable (non-oscillating geometries)
Stability Curves for TAOs in He

\[ \alpha \]

\[ \xi = 1 \]

Y. Gu
PhD Thesis
University of Colorado 1993

June 2019
Lecture 14 | Cryogenic Instrumentation - J. G. Weisend II

Slide 24
Using the Stability Curves

\[ \alpha = \frac{T_H}{T_C} \]

\[ \xi = \frac{L_H}{L_C} \]

Where the division between \( L_H \) and \( L_C \) is the point in the tube where \( T = \frac{(T_H + T_C)}{2} \)

These curves are for a 1 meter long tube. To use them with other lengths use the Adjusted radius:

\[ r' = \frac{r}{\sqrt{L}} \]

Stability on the left hand side of the plots is due to viscous damping and stability on the right hand side of the plots is due to inertial damping.
Other Approaches to Removing TAOs

- Add volume to the warm end
- Install a check valve between the warm and cold end (near boundary between the two) – this converts the problem to a closed cold tube with no TAOs
- Heat sink the closed end (thus changing $T_H/T_C$)
- Allow flow through the warm end
