STOPPING POWER ~~ALP~~

## Stopping Power

- The average **linear rate of energy loss** of a heavy charged particle in a medium ( $\text{MeV cm}^{-1}$ ) is of fundamental importance in radiation physics, dosimetry and radiation biology.
- This quantity, designated  $-dE/dx$ , is called the **stopping power** of the medium for the particle.
- It is also referred to as the **linear energy transfer (LET)** of the particle, usually expressed as  $\text{keV } \mu\text{m}^{-1}$  in water.
- **Stopping power** and **LET** are closely associated with the dose and with the **biological effectiveness** of different kinds of radiation.

## Calculations of Stopping Power

In 1913, Niels Bohr derived an explicit formula for the stopping power of heavy charged particles.

Bohr calculated the energy loss of a heavy charged particle in a collision with an electron, then averaged over all possible distances and energies.

## The Bethe Formula for Stopping Power.

Using relativistic quantum mechanics, Bethe derived the following expression for the stopping power of a uniform medium for a heavy charged particle:

$$-\frac{dE}{dx} = \frac{4\pi k_0^2 z^2 e^4 n}{mc^2 \beta^2} \left[ \ln \frac{2mc^2 \beta^2}{I(1-\beta^2)} - \beta^2 \right].$$

$k_0 = 8.99 \times 10^9 \text{ N m}^2 \text{ C}^{-2}$ , (the Boltzman constant)

$z$  = atomic number of the heavy particle,

$e$  = magnitude of the electron charge,

$n$  = number of electrons per unit volume in the medium,

$m$  = electron rest mass,

$c$  = speed of light in vacuum,

$\beta = V/c$  = speed of the particle relative to  $c$ ,

$I$  = mean excitation energy of the medium.

- Only the **charge**  $ze$  and **velocity**  $V$  of the heavy charged particle enter the expression for stopping power.
- For the medium, only the **electron density**  $n$  is important.

## Tables for Computation of Stopping Powers

If the constants in the Bethe equation for stopping power,  $dE/dX$ , are combined, the equation reduces to the following form:

$$-\frac{dE}{dx} = \frac{5.08 \times 10^{-31} z^2 n}{\beta^2} [F(\beta) - \ln I_{ev}] \text{ MeV cm}^{-1}$$

$$\text{where, } F(\beta) = \ln \frac{1.02 \times 10^6 \beta^2}{1 - \beta^2} - \beta^2$$

**TABLE 5.2. Data for Computation of Stopping Power for Heavy Charged Particles**

OPTIONAL

6

**Conveniently,.....**

For a given value of  $\beta$ , the kinetic energy of a particle is proportional to the rest mass,

*Table 5.2 can also be used for other heavy particles.*

*Example:*

The ratio of kinetic energies of a deuteron and a proton **traveling at the same speed** is

$$\frac{\frac{1}{2}M_d V^2}{\frac{1}{2}M_p V^2} = \frac{M_d}{M_p} = 2$$

Therefore the value of  $F(\beta)$  of 9.972 for a 10 MeV proton, also applies to a 20 MeV deuteron.

# MEAN EXCITATION ENERGIES

2

$I_1$  HAVE BEEN CALCULATED USING Q.M. OR  
~~CALCULATED~~ EXPERIMENTALLY DETERMINED.

EMPIRICAL FORMULAS FOR  $I$  [eV]

CAN BE USED FOR ATOMIC NUMBER  $Z$

$$I \approx 19.0 \text{ eV} \quad Z=1 \quad (\text{i.e. HYDROGEN})$$

$$I \approx 11.2 \text{ eV} + (11.7)(Z) \text{ eV} \quad 2 \leq Z \leq 13$$

$$I \approx 52.8 \text{ eV} + (8.71)(Z) \text{ eV} \quad Z > 13$$

COMPOUNDS OR MIXTURES THE WEIGHTED CONTRIBUTIONS  
MUST BE CONSIDERED.

THE COMPOSITE  $\ln(I_{\text{eV}})$  VALUE IS OBTAINED FROM  
WEIGHTED CONTRIBUTION OF THE  $e^-$  DENSITIES IN THE  
VARIOUS ELEMENTS.

$$N \ln I = \sum_i N_i Z_i \ln I_i \quad N = \text{TOTAL \# } e^- \text{ IN MATERIAL}$$

QUICK EXAMPLE

CALCULATE THE MEAN EXCITATION ENERGY OF WATER

I<sub>H</sub> = 19.0 eV

I<sub>O</sub> = 11.2 + 11.7 × 8 = 105 eV

~~N<sub>i</sub> Z<sub>i</sub>~~ RATIO OF e<sup>-</sup> TO TOTAL e<sup>-</sup>,  $\pi$

NUM BER OF ATOMS →  $\frac{N_i Z_i}{\pi}$  ← # e<sup>-</sup> FROM ATOMIC #

H<sub>2</sub>O ⇒ TOTAL 10 e<sup>-</sup>

$\ln I = \frac{2 \text{ atoms} \times 7 e^-}{10 e^-} \ln(19.0 \text{ eV}) + \frac{1 \times 8}{10} \ln(105) = 4.312$

I = 74.6 eV

## Stopping power versus distance: the Bragg Peak

$$-\frac{dE}{dx} = \frac{5.08 \times 10^{-31} z^2 n}{\beta^2} [F(\beta) - \ln I_{ev}] \text{ MeV cm}^{-1}$$

- At low energies, the factor in front of the bracket increases as  $\beta \rightarrow 0$ , causing a peak (called the Bragg peak) to occur.
- The linear rate of energy loss is a maximum as the particle energy approaches 0.

[Image removed due to copyright considerations]

Rate of energy loss along an alpha particle track.

- The peak in energy loss at low energies is exemplified in the Figure, above, which plots  $-dE/dx$  of an alpha particle as a function of distance in a material.
- For most of the alpha particle track, the charge on the alpha is two electron charges, and the rate of energy loss increases roughly as  $1/E$  as predicted by the equation for stopping power.
- Near the end of the track, the charge is reduced through electron pickup and the curve falls off.

SKIP

**Stopping Power of Water for Protons**

$$-\frac{dE}{dx} = \frac{5.08 \times 10^{-31} z^2 n}{\beta^2} [F(\beta) - \ln I_{ev}] \text{ MeV cm}^{-1}$$

What is needed to calculate **stopping power**,  $-dE/dX$ ?

- n the electron density
- z the atomic number
- $\ln I$  the mean excitation energy

For protons,  $z = 1$ ,

The gram molecular weight of water is 18.0 g/mole and the number of electrons per molecule is 10.

One  $\text{m}^3$  of water has a mass of  $10^6$  g.

The density of electrons,  $n$ , is:

$$n = 6.02 \times 10^{23} \text{ molecules/mole} \times \frac{10^6 \text{ g m}^{-3}}{18.0 \text{ g/mole}} \times 10 \text{ e}^-/\text{molecule} = 3.34 \times 10^{29} \text{ electrons/m}^3$$

As found above, for water,  $\ln I_{ev} = 4.312$ . Therefore, eq (1) gives

$$-\frac{dE}{dx} = \frac{0.170}{\beta^2} [F(\beta) - 4.31] \text{ MeV cm}^{-1}$$

At 1 MeV, from Table 5.2,  $\beta^2 = 0.00213$  and  $F(\beta) = 7.69$ , therefore,

$$-\frac{dE}{dx} = \frac{0.170}{0.00213} [7.69 - 4.31] = 270 \text{ MeV cm}^{-1}$$

*The stopping power of water for a 1 MeV proton is 270 MeV cm<sup>-1</sup>*

## Mass Stopping Power

- The **mass stopping power** of a material is obtained by dividing the stopping power by the density  $\rho$ .
- Common units for mass stopping power,  $-dE/\rho dx$ , are  $\text{MeV cm}^2 \text{g}^{-1}$ .
- The mass stopping power is a useful quantity because it expresses the rate of energy loss of the charged particle per  $\text{g cm}^{-2}$  of the medium traversed.
- In a gas, for example,  $-dE/dx$  depends on pressure, but  $-dE/\rho dx$  does not, because dividing by the density exactly compensates for the pressure.
- Mass stopping power does not differ greatly for materials with similar atomic composition.
- Mass stopping powers for water can be scaled by density and used for tissue, plastics, hydrocarbons, and other materials that consist primarily of light elements.

For Pb ( $Z=82$ ), on the other hand,  $-dE/\rho dx = 17.5 \text{ MeV cm}^2 \text{g}^{-1}$  for 10-MeV protons. (water  $\sim 47 \text{ MeV cm}^2 \text{g}^{-1}$  for 10 MeV protons)

\*\*Generally, heavy atoms are less efficient on a  $\text{g cm}^{-2}$  basis for slowing down heavy charged particles, because many of their electrons are too tightly bound in the inner shells to participate effectively in the absorption of energy.

## Range

The **range** of a charged particle is the distance it travels before coming to rest.

The range is **NOT** equal to the energy divided by the stopping power.

Table 5.3 [Turner] gives the mass stopping power and range of protons in water. The range is expressed in  $\text{g cm}^{-2}$ ; that is, the range in cm multiplied by the density of water ( $\rho = 1 \text{ g cm}^{-3}$ ).

Like mass stopping power, the range in  $\text{g cm}^{-2}$  applies to all materials of similar atomic composition.

### A useful relationship.....

For two heavy charged particles *at the same initial speed*  $\beta$ , the ratio of their ranges is simply

$$\frac{R_1(\beta)}{R_2(\beta)} = \frac{z_2^2 M_1}{z_1^2 M_2},$$

where:

$R_1$  and  $R_2$  are the ranges  
 $M_1$  and  $M_2$  are the rest masses and  
 $z_1$  and  $z_2$  are the charges

If particle number 2 is a proton ( $M_2 = 1$  and  $z_2 = 1$ ), then the range  $R$  of the other particle is given by:

$$R(\beta) = \frac{M}{z^2} R_p(\beta),$$

where  $R_p(\beta)$  is the proton range.

TABLE 5.3. Mass Stopping Power  $-dE/\rho dx$  and Range  $R_p$  for Protons in Water

Kinetic Energy (MeV)	$\beta^2$	$-dE/\rho dx$ (MeV cm <sup>2</sup> g <sup>-1</sup> )	$R_p$ (g cm <sup>-2</sup> )
0.01	.000021	500.	$3 \times 10^{-5}$
0.04	.000085	860.	$6 \times 10^{-5}$
0.05	.000107	910.	$7 \times 10^{-5}$
0.08	.000171	920.	$9 \times 10^{-5}$
0.10	.000213	910.	$1 \times 10^{-4}$
0.50	.001065	428.	$8 \times 10^{-4}$
